

Objective

The objective of this Project was to design and construct a remote follower Self-Lavelling Platform that incorporated the concepts developed from utilising a non-dispersive Amici Roof Prism with linearly Polarized Light, produced by using two laser sources. The purpose was to let one platform follow another one in direction of angle of rotation either clockwise or counter-clockwise.

Polarization Filter

Polarization filter is a filter used to pass a laser beam and usually followed by an analyser which is another polarizer filter. The beam intensity out of the two filters depends on the angle between them.

Polarization Filter

Polarization Filter

When to Amici Prism is rotated, one of the split image direction of Polarization will increase in intensity, while the other split image direction of Polarization will decrease in intensity, as the sensors detect increase / decrease in Light intensities according to Malus Law intensities.

Project Concept

The op-amp amplifiers implementation

The Hardware circuit

Operation

The operation of the project hardware is based on laser beam as input and the interfaces and the attenuation are through polarizer and amici prism then the interaction is done through an electrical circuit that converts the optic signal to electric signal and process the voltage levels and based on that a proper action is executed rotating the stepper motor.
